ABSTRACT

On the basis of the revision of the type material of *Aspiculuris ackerti* Kruidenier & Mehra, 1959, and new specimens collected from *Neotoma nelsoni* Goldman, 1905 (Rodentia: Cricetidae), in Veracruz, Mexico, we herein describe a new genus (*Lamotheoxyuris* n. gen.), to which *A. ackerti* is transferred as *Lamotheoxyuris ackerti* (Kruidenier & Mehra, 1959) n. gen., n. comb. This new genus differs from all other genera included in Heteroxynematinae by the following main traits: 1) mouth surrounded by six lips; 2) extension of lateral alae reduced; and 3) lack of caudal alae.

Key words: *Aspiculuris ackerti*, Mexico, Nematoda, Rodentia, USA.

RESUMEN

Con base en la revisión del material tipo de *Aspiculuris ackerti* Kruidenier y Mehra, 1959 y de nuevos ejemplares recolectados en *Neotoma nelsoni* Goldman, 1905 (Rodentia: Cricetidae), en Veracruz, México, se describe un nuevo género (*Lamotheoxyuris* n. gen.), al que *A. ackerti* es transferido como *Lamotheoxyuris ackerti* (Kruidenier y Mehra, 1959) n. gen., n. comb. Este nuevo género se distingue de todos los demás géneros incluidos en Heteroxynematinae por las siguientes características: 1) presencia de seis labios rodeando la boca; 2) extensión reducida del ala lateral; y 3) carencia de ala caudal.

Palabras clave: *Aspiculuris ackerti*, México, Nematoda, Rodentia, USA.

INTRODUCTION

Aspiculuris ackerti Kruidenier & Mehra, 1959 was described as a parasite of *Neotoma albigena* Hartley, 1894 and *Neotoma cinerea* Ord, 1815 in Arizona (Kruidenier & Mehra 1959). Since then, the validity of its classification has been questioned several times. Hugot (1980) pointed out that *A. ackerti* does not possess the generic characteristics to support its placement in the genus *Aspiculuris* Schulz, 1924. In a re-description of *A. ackerti*, Miller & Schmidt (1982) found some discrepancies with respect to the original description, i.e., different number of caudal papillae and morphology of caudal alae. Finally, in agreement with Hugot (1980), Inglis

et al. (1990) considered this nematode as species dubium. Based on the re-examination of type material of this nematode species and in new specimens collected in Veracruz, Mexico from Nelson's woodrat *Neotoma nelsoni* Goldman, 1905, we conclude that *A. ackerti* belongs to a new genus, which is herein described.

The type host of *A. ackerti* (*N. albigena*) is distributed from southeastern California and southeastern Utah to central Texas and from northeastern Michoacán to Hidalgo, Mexico (Macedo & Mares 1988). Other host of this nematode species, *N. cinerea* is found in mountainous areas from the southern Yukon and the westernmost Northwest Territories, south through British Columbia and western

Alberta to northern California, Arizona and New Mexico, and as far east as the western portion of North Dakota (Smith 1997). Finally, *N. nelsoni*, which also hosts *A. ackerti*, is an endemic species of the Oriental Basin of Mexico.

METHODS

One specimen of *N. nelsoni* (Rodentia: Cricetidae) was trapped in the wild using standard methods approved by the American Society of Mammalogists (Gannon et al. 2007). This specimen was collected on 22 June 2007 from El Frijol Colorado, Municipality of Perote, in the state of Veracruz ($19^{\circ}34'20''$ N, $97^{\circ}23'01''$ W, 2,435 masl) and examined for parasites. This locality is characterized by rocky hills with cactus pear, catclaw, agave and yucca. Intestinal nematodes were fixed in 70 % ethanol and cleared with lactophenol for morphometric study. For comparative purposes the following specimen from the U. S. National Parasite Collection (USNPC), Beltsville, Maryland, was examined: *Aspicularis ackerti* Kruidener & Mehra, 1959 [USNPC 056163 (type specimens), 075506 and 088077].

Drawings and measurements were made with a Zeiss microscope equipped with a drawing tube. For scanning electron microscopy (SEM) study, nematodes were dehydrated in graded series ethyl alcohol dilutions and critical-point dried with carbon dioxide. Specimens were coated with a gold-palladium mixture and examined in a Hitachi S-2460N scanning electron microscope at 15 kV. Range is followed by the mean and standard deviation; sample size (n) is provided in parentheses. The host was obtained under the collecting permit FAUT-0002 issued to Fernando Cervantes Reza and is housed at the Museum of Natural Science (Louisiana State University) as specimen number LSUMZ 36663. Voucher specimens of parasites were deposited in the Colección Nacional de Helmintos (CNHE), Instituto de Biología, Universidad Nacional Autónoma de México, Mexico City.

RESULTS

Description of the genus

Lamotheoxyuris n. gen.

Diagnosis: Oxyurida, Heteroxinematidae, Heteroxynematinae. The worms are small in size. Males are shorter than females. Cephalic vesicle present; cervical alae present, extending from the cephalic region to the mid-body in males and before the vulva in females; each cervical alae have two crests (sensu Hugot 1980) in cross section. Lateral alae are reduced in the both sexes. A ventral ala is present in males, beginning at the mid-body region and ending before the cloaca. The mouth is surrounded by six lips, one pair of

lateral "epaulette" with two amphids and four labial papillae. Males without caudal alae. Gubernaculum and spicules are absent. Ten caudal papillae are arranged as follows: one pair precloacal, one pair adcloacal, a single median postcloacal papilla closely associated with the cloaca, one posterior pair followed by one single median papilla, and one additional posterior pair.

Taxonomic summary

Type and only known species: *Lamotheoxyuris ackerti* (Kruidener & Mehra, 1959) n. comb., parasitizing the intestine of *N. albogula*, 1894 from Coconino Co., Arizona, United States of America.

Other records: ex *N. cinerea* from Colorado and Wyoming. *N. albogula* from New Mexico, and *N. nelsoni* from Veracruz, Mexico.

Etymology: The genus is named after Dr. Marcos Rafael Lamothe-Argumedo in commemoration of his 50th anniversary as a scientific researcher in Helminthology.

Remarks

Following Petter & Quentin (1976), our specimens are included in Heteroxynematidae: Heteroxynematinae because the last pair of male postcloacal papillae is isolated near the caudal extremity, the glandular portion of the ovijector is never in the form of an enlarged ring at the distal end of the muscular vagina vera, eggs lacking operculum, and the pharyngeal and buccal structures are simples. To date, Heteroxynematinae comprises 10 genera distributed worldwide (Erkulov 1975, Petter & Quentin 1976, Mas-Coma & Esteban 1982). Two of these 10 genera can be distinguished from the new genus because they are parasites of birds: *Eudromoxyura* Anderson & Prestwood, 1972 and *Syphaciella* Mönnig, 1924, while *Lamotheoxyuris* infects rodents; in addition, *Eudromoxyura* has an intestinal caecum behind the esophageal bulb, which is absent in *Lamotheoxyuris*, and three well developed trilobed lips with small interlabia (vs. six lips without interlabia in the new genus) (Anderson & Prestwood 1972); likewise, the presence of triangular teeth in the vestibule as well as gubernaculum, spicules, and caudal alae allow to differentiate

Syphaciella from *Lamotheoxyuris*, which lacks these structures (Petter & Quentin 1976).

The other eight genera included in Heteroxynematinae (*Aspiculuris* Schulz, 1924; *Dermatopallarya* Skrjabin, 1924; *Dentostomella* Schulz & Krepkogorskaja, 1932; *Fastigiuris* Babaev, 1966; *Heteroxynema* Hall, 1916; *Ivaschkinonema* Erkulov, 1975; *Kahmannia* Mas-Coma & Esteban, 1982, & *Rauschoxyuris* Quentin, 1975) parasitize mammals, as does the new genus. However, two of them (*Dentostomella* and *Kahmannia*) lack cervical alae (present in *Lamotheoxyuris*), and have esophageal teeth and a single spicule (both characteristics absent in the new genus) (Petter & Quentin 1976, Skrjabin 1982, Mas-Coma & Esteban 1982). The species included in the remaining six genera that parasitize mammals have cervical alae like *Lamotheoxyuris ackerti*. However, the new genus differs from all these genera by the following main characteristics: *Dermatopallarya* have three lips and a defined buccal cavity instead of six lips and a mouth opening directly to the esophagus, as in the new genus; in addition, males of *Dermatopallarya* possess two ventral cuticular swellings, which are absent in the new genus (Petter & Quentin 1976, Skrjabin 1982); the esophageal bulb in *Fastigiuris* is reduced or absent whereas this structure is well developed in the new genus; also, the cervical alae in *Fastigiuris* are markedly bent in the ventral region (Petter & Quentin 1976) while the cervical alae are straight in the specimens described in this study. Likewise, *Lamotheoxyuris* can be differentiated from *Heteroxynema* because males of this later genus have a precloacal pseudosucker, gubernaculum, and a spicule (Petter & Quentin 1976, Hugot & Sutton 1989), which are all lacking in the new genus. *Ivaschkinonema* possesses four differentiated lips and caudal rings (Erikulov 1975), whereas *Lamotheoxyuris* has six lips and lacks caudal rings. Finally, *Rauschoxyuris* has a precloacal denticulate crest (Quentin 1975), that is absent in the new genus.

The new genus most closely resembles to *Aspiculuris*. Nevertheless, both genera can be distinguished based on the following traits: 1) *Aspiculuris* has caudal alae (absent in *Lamotheoxyuris*); 2) lateral alae in *Aspiculuris* run along the body, while the lateral alae only reach the mid-body region in the new genus; 3) cervical alae in *Aspiculuris* narrow posteriorly to

give a spearhead-like or an arrowhead-like outline to the cephalic end, differentiating it from lateral alae; in *Lamotheoxyuris*, the cervical alae are continuous with the lateral alae, with no superficial distinction; 4) cross sections of cervical and lateral alae in our material, showed the same morphology, being constituted by two crests along its extension; in *Aspiculuris* spp., cross sections of cervical alae showed two crests, while the lateral alae had only one crest [for examples, see Figs. 1C, 1D, and 1E for *Aspiculuris tetraptera* (Nitzsch, 1821), and Figs. 3J, 3K, 3L, and 3M for *Aspiculuris africana* Quentin, 1966 in Hugot (1980); finally, 5) the mouth in *Aspiculuris* is surrounded by three undivided lips, while *L. ackerti* possesses six lips that are clearly differentiated by SEM. Observations of the anterior end of *A. ackerti* in face view, made by Miller & Schmidt (1982) with light microscopy, could not establish the true number of lips.

Description of the species

Lamotheoxyuris ackerti (Kruidener & Mehra, 1959) n. gen., n. comb.
(Figs. 1-3)

Male: Based on six mature specimens. Body small, cylindrical. Length 3.10-3.74 mm (3.58 mm ± 0.29 mm, n = 6); width 154-182 µm (163 µm ± 11 µm, n = 6) at mid-body. Cephalic vesicle 98-126 µm long (117 µm ± 11 µm, n = 6) by 84-112 µm wide (98 µm ± 9 µm, n = 6). Total esophagus length 291-360 µm (337 µm ± 26 µm, n = 6); esophageal bulb 105-132 µm (121 µm ± 9 µm, n = 6) long by 54-66 µm (60 µm ± 4 µm, n = 6) wide. Distance from anterior end to nerve ring 141-150 µm (146 µm ± 4 µm, n = 6), to excretory pore 717-735 µm (723 µm ± 10 µm, n = 3). Excretory pore posterior to junction of esophageal bulb and intestine. Cervical alae beginning 30-36 µm (26 µm ± 3 µm, n = 3) from anterior end; it will continue with a short lateral alae which ends at midbody. Distance from cloaca to tip of tail 87-117 µm (108 µm ± 11 µm, n = 6). Ten caudal papillae arranged as follow: one precloacal pair, one adcloacal pair, a single medial postanal pair closely associated with cloaca, one posterior pair followed by one single median (located between two long and straight cuticular thickenings), and one additional posterior pair.

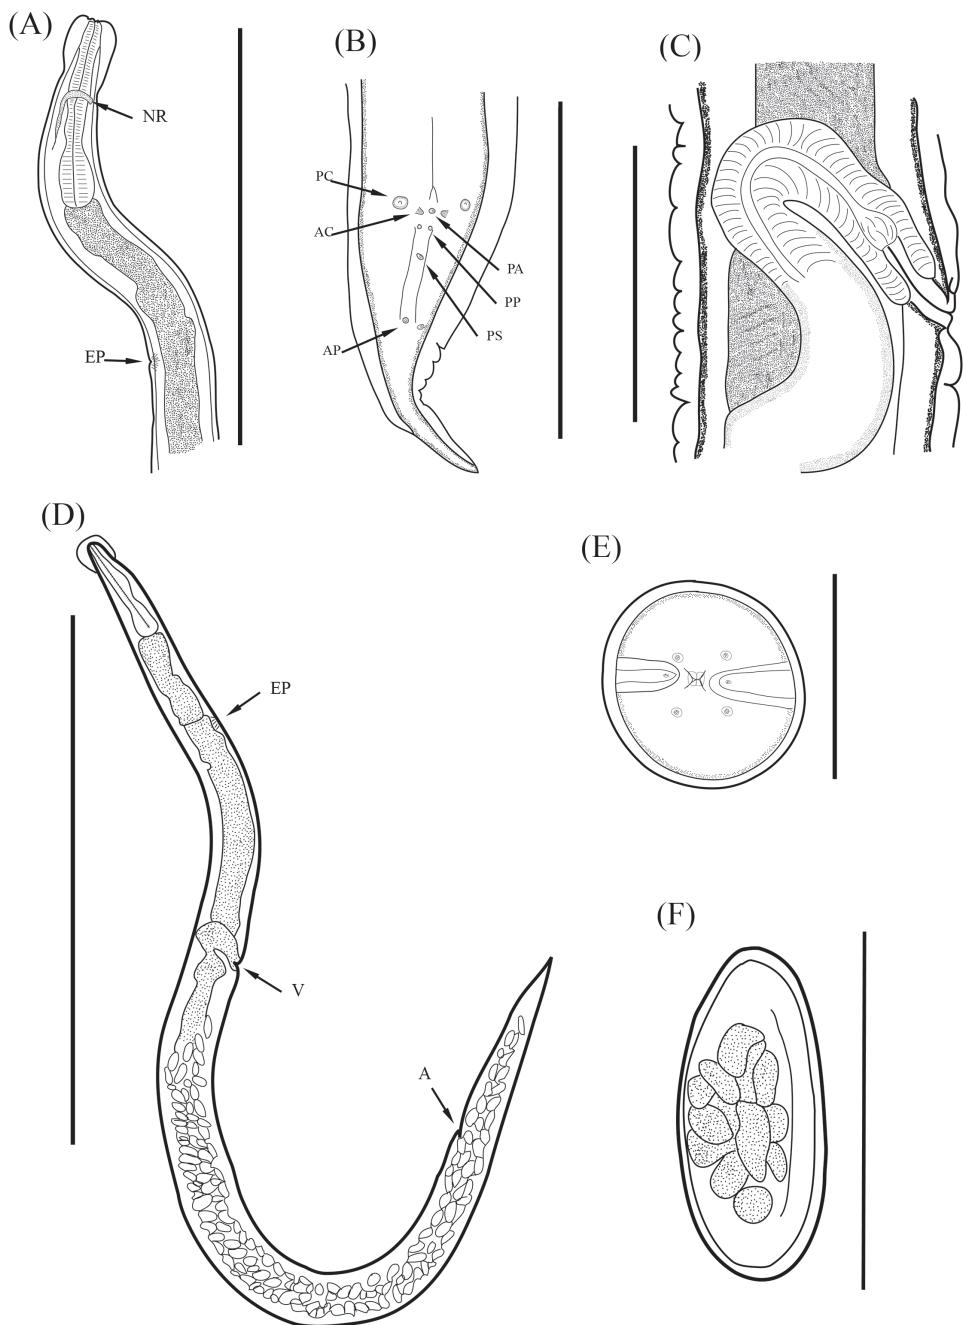

Fig. 1: Lamotheoxyuris ackerti n. gen., n. comb., from *Neotoma nelsoni*. Male: A) Anterior end, lateral view (NR = nerve ring; EP = excretory pore). Bar = 1.0 mm; B) Detail of posterior end of male, arrangement of caudal papillae (PC = 1 precloacal pair; AC = 1 adcloacal pair; PA = single medial postanal; PP = 1 posterior pair; PS = 1 single median; AP = 1 additional posterior pair). Bar = 250 µm. Female: C) Ovejector region. Bar = 200 µm. D) Entire, lateral view (EP = excretory pore; V = vulva; A = anus). Bar = 2.0 mm. E) In face view showing lips, papillae and "epaulettes". Bar = 100 µm. F) Eggs. Bar = 100 µm.

Lamotheoxyuris ackerti n. gen., n. comb., de *Neotoma nelsoni*. Macho: A) Extremo anterior, vista lateral (NR = anillo nervioso; EP = poro excretor). Escala = 1.0 mm; B) Detalle del extremo posterior del macho, disposición de las papilas caudales (PC = 1 par precloacal; AC = 1 par adcloacal; PA = papila postanal media; PP = 1 par postcloacal; PS = 1 papila media; AP = 1 par posterior adicional. Escala = 250 µm. Hembra: C) Región del Oviector. Escala = 200 µm. D) Ejemplar completo, vista lateral (EP = poro excretor; V = vulva; A = ano). Escala = 2.0 mm. E) Vista frontal mostrando los labios, papillas y "epaulettes". Escala = 100 µm. F) Huevos. Escala = 100 µm.

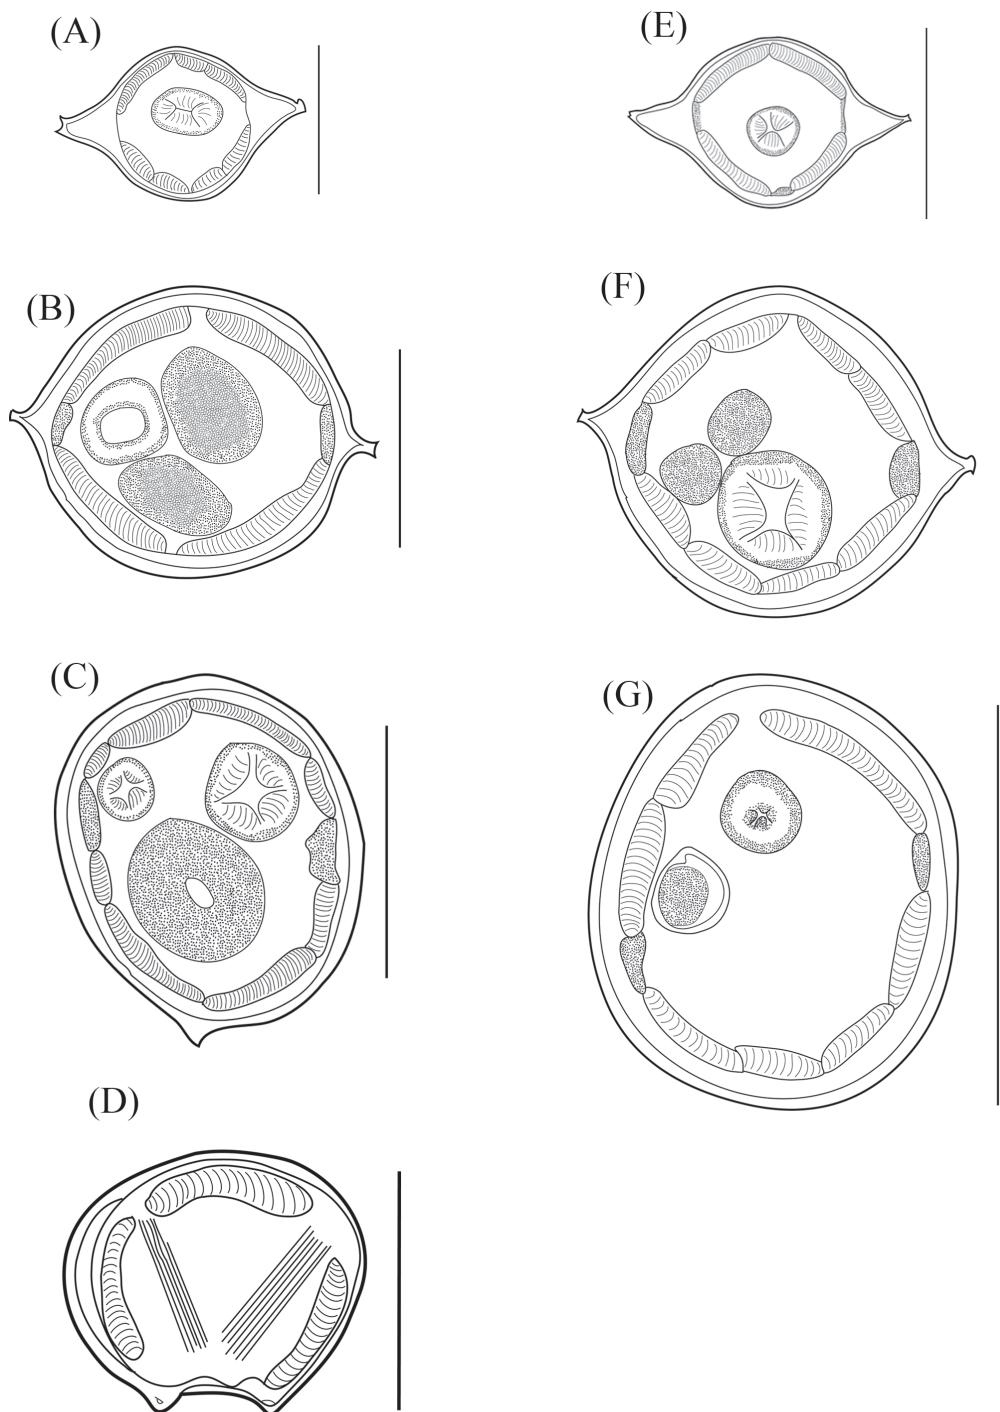

Fig. 2: Lamotheoxyuris ackerti n. gen., n. comb., from *Neotoma nelsoni*. Male, cross section: A) Esophagus level. Bar = 100 µm. B) End of alae. Bar = 100 µm. C) Caudal region 150 µm. D) Postcloacal region. Bar = 100 µm. Female cross section: E) Esophagus level. Bar = 150 µm. F) Close to the vulva. Bar = 200 µm. G) Ovejector level. Bar = 200 µm.

Lamotheoxyuris ackerti n. gen., n. comb., de *Neotoma nelsoni*. Macho, corte transversal: A) A nivel del esófago. Escala = 100 µm. B) A nivel del final del ala lateral. Escala = 100 µm. C) En la región caudal. Escala = 150 µm. D) En la región postcloacal. Escala = 100 µm. Hembra, corte transversal: E) A nivel del esófago. escala = 150 µm. F) Cercano a la vulva. Escala = 200 µm. G) A nivel del oviector. Escala = 200 µm.

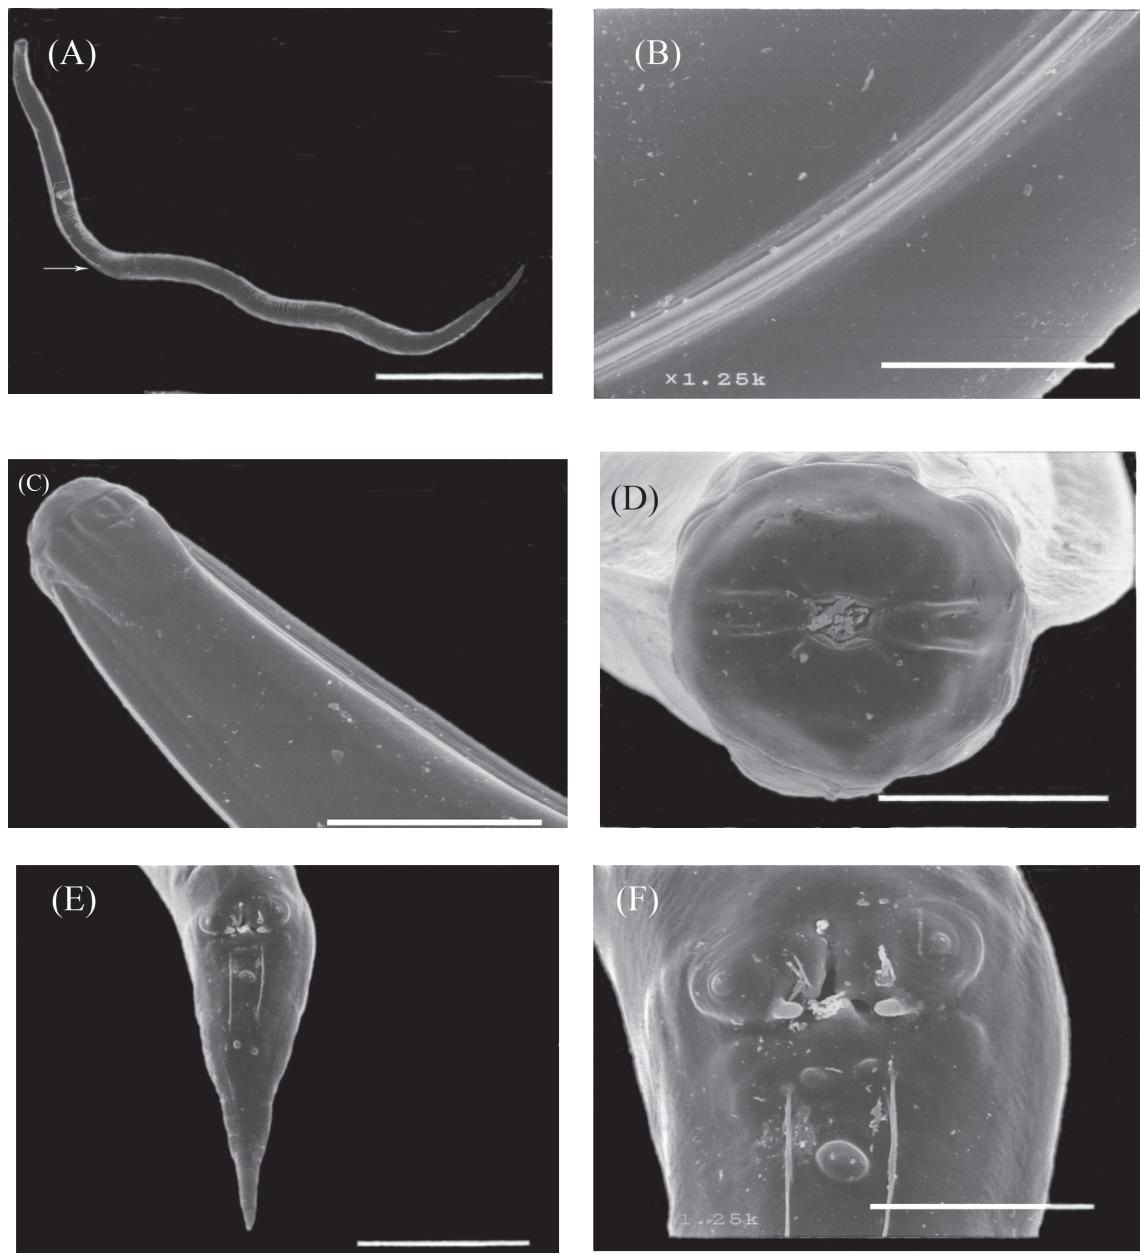

Fig. 3: Lamotheoxyuris ackerti n. gen., n. comb., from *Neotoma nelsoni*. Male: A) Total view. Bar = 1 mm; white arrow indicates final of lateral alae; B) Lateral ala, lateral view. Bar = 40 μ m. C) Detail of anterior end, dorsal view. Bar = 100 μ m. D) Mouth apical view Bar = 40 μ m; E) Caudal sessile papillae, ventral view. Bar = 100 μ m. F) Detail of caudal papillae. Bar = 40 μ m.

Lamotheoxyuris ackerti n. gen., n. comb., de *Neotoma nelsoni*. Macho: A) Vista total. Escala = 1 mm; la flecha blanca indica el final del ala lateral; B) ala lateral, vista lateral. Escala = 40 μ m. C) Detalle del extremo anterior, vista dorsal. Escala = 100 μ m. D) Boca, vista apical. Escala = 40 μ m; E) Papilas caudales sésiles, vista ventral. Escala = 100 μ m. F) Detalle de las papilas caudales. Escala = 40 μ m.

Female: Based on 11 mature specimens. Length at mid-body 4.558-5.663 mm (5.045 mm \pm 0.33 mm, n = 11); width 21-224 μ m (218 μ m \pm 7 μ m, n = 11). Cephalic vesicle 112-168 μ m

long (139 μ m \pm 13 μ m, n = 11) by 112-126 μ m wide (115 μ m \pm 8, n = 11). Total esophagus length 369-465 μ m (404 μ m \pm 27 μ m, n = 11); esophageal bulb 120-150 μ m (135 μ m \pm 10 μ m,

$n = 11$) long, 66-84 μm ($77 \mu\text{m} \pm 5 \mu\text{m}$, $n = 11$) wide. Distance from anterior end to nerve ring 135-156 μm ($145 \mu\text{m} \pm 6 \mu\text{m}$, $n = 11$), to excretory pore 639-804 μm ($720 \mu\text{m} \pm 50 \mu\text{m}$, $n = 10$). Cervical alae beginning 27-45 μm ($33 \mu\text{m} \pm 6 \mu\text{m}$, $n = 9$) from anterior end; it will continue with a short lateral alae which ends before to vulva. Vulva pre-equatorial, opening 1.6-2 mm ($1.79 \text{ mm} \pm 0.128 \text{ mm}$, $n = 10$) from anterior end. Ovejector 249-264 μm ($256 \mu\text{m} \pm 11 \mu\text{m}$, $n = 2$) long. Distance from caudal extremity to anus 591-660 μm ($618 \mu\text{m} \pm 26 \mu\text{m}$, $n = 6$); eggs 78-90 μm ($86 \mu\text{m} \pm 4 \mu\text{m}$) long by 30-39 μm ($34 \mu\text{m} \pm 2 \mu\text{m}$) wide ($n = 66$ eggs).

Taxonomic summary

Type host: *Neotoma albicula* Hartley, 1894; (Rodentia: Cricetidae).

Site of infection: Intestine.

Type locality: Coconino County, Arizona.

Other hosts: *Neotoma cinerea* (Ord, 1815); *N. nelsoni* Goldman, 1905.

Other localities: Weld Co., Colorado and Laramie Co., Wyoming (Miller & Schmidt 1982); Sorocco Co., New Mexico (USNPC 88077, identified by M. D. Dailey); 3 km S El Frijol Colorado ($19^{\circ}34'20''$ N, $97^{\circ}23'0.7''$ W, elevation: 2,435 m), Perote, Veracruz, Mexico.

Specimens deposited: CNHE 6839.

Synonym: *Aspiculuris ackerti* Kruidener & Mehra, 1959.

DISCUSSION

Aspiculuris ackerti was described by Kruidener & Mehra (1959) who justified the inclusion of this species in *Aspiculuris* based on the presence of cervical alae with a gradual anterior-posterior narrowing (as in *A. asiatica* Schulz, 1927) and the presence of "two deep notches each" in the caudal alae of males (Kruidener & Mehra 1959, pp. 148). This species was re-described by Miller & Schmidt (1982) who pointed out that the cervical alae narrow smoothly and continue posterior as narrow lateral alae.

Unlike Kruidener & Mehra (1959), Miller & Schmidt (1982, pp. 112) observed only one

deep notch in the caudal alae of males, which gives "the superficial appearance of being paired" to the alae. Based on our examination of the type material of *A. ackerti* (USNPC 056163) and new specimens from *N. nelsoni* from Mexico, we determined that caudal alae do not exist in this species. What appeared to be caudal alae to Kruidener & Mehra (1959) and Miller & Schmidt (1982) look more like cuticular inflation under light microscopy. Subsequently SEM examination of these structures and cross sections of the body at this level showed that males of *A. ackerti* lack caudal alae altogether.

This is the first report of a helminth parasite occurring in Nelson's woodrat *N. nelsoni*, which is endemic and endangered species in Mexico. Prior to this study, distribution of this woodrat was restricted to only three locations in the states of Veracruz and Puebla (Hall & Dalquest 1963, Hall 1981, González-Christen et al. 2002; González-Ruiz et al. 2006). Herein, we reported a fourth locality for this species in Veracruz, Mexico.

ACKNOWLEDGMENTS

We thank Fernando Cervantes for providing collection permits. Eric Hoberg and Patricia Pillit, from USNPC, have kindly lent us the type specimens of *A. ackerti*. Juan Carlos Winfield-Pérez helped collecting rodents in the field and Berenit Mendoza-Garfias for assisting in processing samples for SEM. The Department of Biological Sciences and the Museum of Natural Science, Louisiana State University and the Instituto de Biología of the Universidad Nacional Autónoma de México provided financial support for field work. We thank Mark S. Hafner for critical comments on the manuscript. This paper was conducted while J.F.O. was a Postdoctoral Fellow in the Laboratorio de Morfología Animal, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo, supported by a fellowship grant: "Estancias posdoctorales y sabáticas vinculadas al fortalecimiento de la calidad del posgrado nacional 2008", from Consejo Nacional de Ciencia y Tecnología (CONACyT).
